3. Renaming. We seldom choose the best names on the first shot, and good names make programs self-explanatory, so renaming is a very important and commonplace action. But in the following simple Haskell program, if we change the name from "helloworld" to "hello" and don't re-indent the rest of the lines, we will get a parse error.

```
helloworld z = let x = 1
```

```
    y = 2 in
    x+y+z
```

Because the code becomes the following after the renaming, and the second line will no longer be aligned to "x = ...", and that confuses the parser.

```
helloworld z = let x = 1 <pre> tag
```
